Professor Joshua Lederberg

Dear Dr. Miller--

Do you know of any studies on the possibility that smoking may be the leukemogen? (for congenital leukemia).

Pinning a 15% reduction on cautions on obstr. X-rays seems to imply  $\underline{1}$ ) a drastic reduction in exposure (can it be more than 1 r per capita?), and  $\underline{2}$ ) a sensitivity >>  $10^{-7}$  per r, which is not particularly borne out by the Hiroshima data.

Your earlier papers seemed more skeptical about this particular etiology; anything new to change your mind?

I think you pointed out yourself that the X-ray "users" would be an atypical sample; it would be interesting and important to derive specific correlations between X-ray exposure and use of various, drugs, smoking, etc. The NINDS perinatal morbidity study should be very good for that, even if not large enough to be too fruitful vis-a-vis leukemic outcome.

Sinverely.
